#### 一 算法原理

算术编码的主要思想是计算输入信源符号序列所对应的区间,然后在区间中间任取一点,以二进制表示适当截断作为序列的编码结果。

算术编码用到两个基本的参数:符号的概率和它的编码间隔。信源符号的概率决定压缩编码的效率,也决定编码过程中信源符号的间隔,而这些间隔包含在0到1之间。编码过程中的间隔决定了符号压缩后的输出。

算术编码方法是将被编码的一则消息或符号串(序列)表示成 0 和 1 之间的一个间隔,即对一串符号直接编码成[0,1]区间上的一个浮点小数。符号序列越长,编码表示它的间隔越小,表示这一段间隔所需的位数也就越多。信源中的符号序列任然需要根据某种模式生成概率的大小来减少间隔。可能出现的符号概率要比不太可能出现的符号减少范围小,因此,只正加较少的比特位。

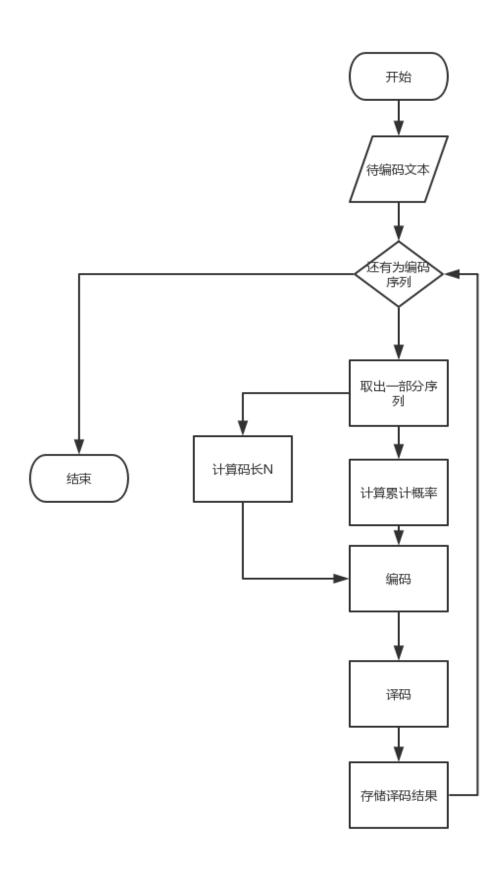

在传输任何符号串之前, 0 符号串的完整范围设置为[0,1]。当一个符号被处理时, 这一范围就依据分配这一符号的范围变窄。算术编码的过程, 实际上就是依据信源符号的发生概率对码区间进行分割的过程。

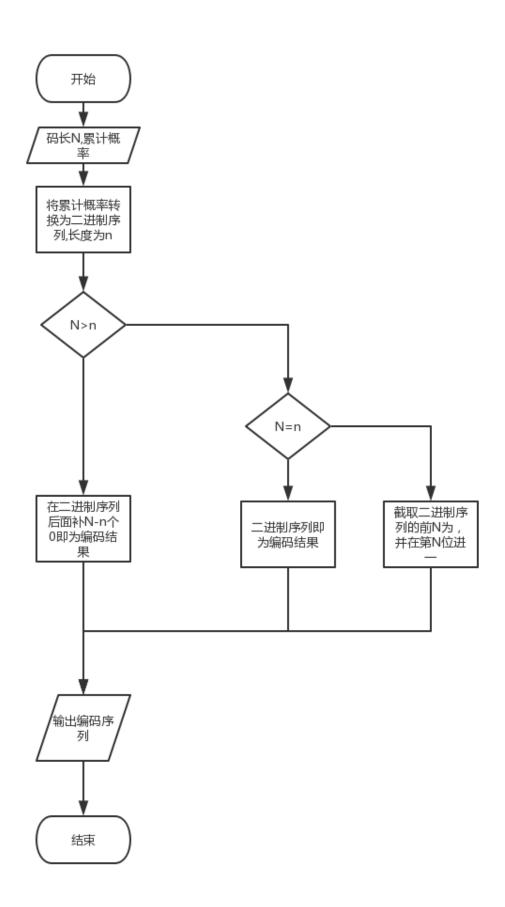

给定事件序列的算术编码步骤如下:

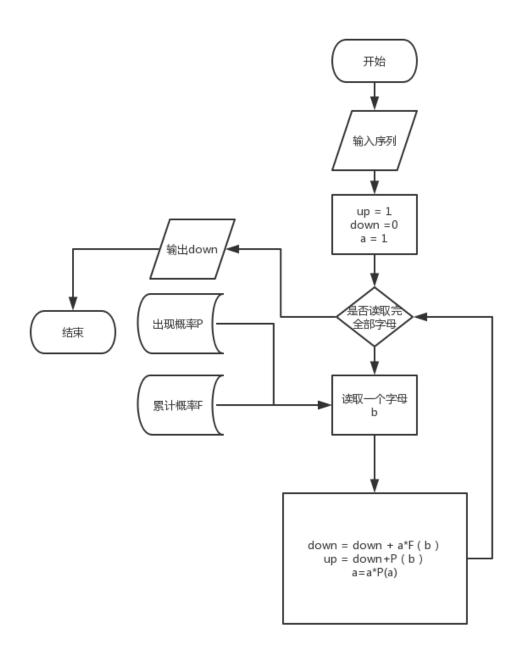

- (1) 编码器在开始时将"当前间隔" [L, H) 设置为[0, 1)。
- (2) 对每一事件, 编码器按步骤(a) 和(b) 进行处理
- (a) 编码器将"当前间隔"分为子间隔,每一个事件一个。
- (b) 一个子间隔的大小与下一个将出现的事件的概率成比例,编码器选择 子间隔对应于下一个确切发生的事件相对应,并使它成为新的"当前间隔"。

 $P(u_i)F(u_{i+1})$ 的大小, $u_i$ 为前面已经译出的字符串序列, $F(u_i)$ 是 $u_i$ 的分布函数,即 $u_i$ 对应区间的下界, $P(u_i)F(u_{i+1})$ 是此区间内下一个输入符号 $u_{i+1}$ 所占区间的宽度,对于 K 元信源,译每一个码元最多需要 K-1 次比较以确定 $u_{i+1}$ 是信源符号集中的哪一个。

# 二 算法流程框图

### 三 实验过程

#### 1. 测试文档 (test.txt)

Financial regulators in Britain have imposed a rather unusual rule on the bosses of big banks. Starting next year, any guaranteed bonus of top executives could be delayed 10 years if their banks are under investigation for wrongdoing. The main purpose of this "clawback" rule is to hold bankers accountable for harmful risk-taking and to restore public trust in financial institutions. Yet officials also hope for a much larger benefit: more long-term decision making, not only by banks but by all corporations, to build a stronger economy for future generations.

#### 2. 实验代码 (Python 实现)

```
# -*-coding:utf-8-*-
import time
import numpy as np
import pprint
import matplotlib.pyplot as plt
import random

## 四 实验结果及分析

译码后的文档: (result.txt)

financial regulators in britain have imposed a rather unusual rule on the bosses of big banks—starting next year—any guaranteed bonus of top executives could be delayed—years if their banks are under investigatin

m

for wrongdoing the main purpose of this clawback yrule is to hold bankers accountable for harmful risk takingsand to restore public trust in financial

institutiontabyet officials also hope for a much larger benefit more long term

decision making not only by banks but by all corporationtaato build a stronger economy for future

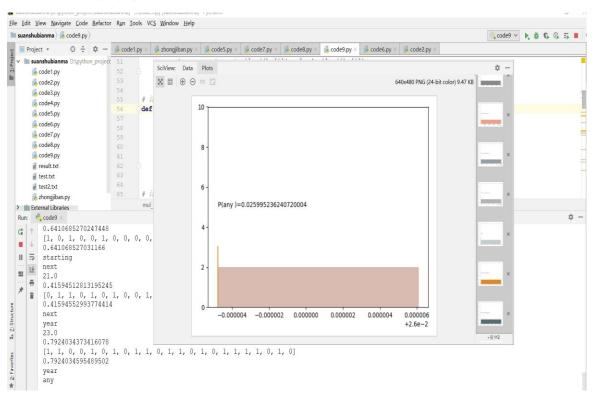

#### 分析:

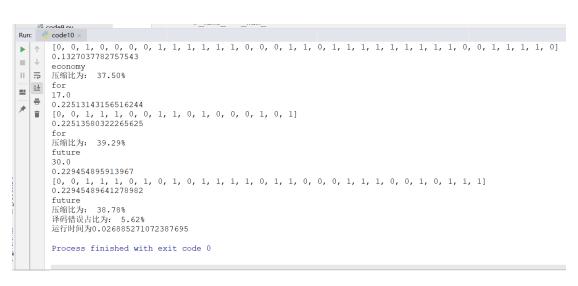

- 1. 由于所给信源符号集中只有小写字母及空格, 所以在编码过程中我将大写转换为小写, 将除空格外的符号全部转换为空格。
- 2. 由于 Python 的浮点数精度只有小数点后 17 位,所以每次编码的序列长度 不能过长,当字符串序列长度过长时,序列区间越来越小,计算机不能精确 识别,导致译码错误,由于我是以空格来作为字符串的结束标志,所以每次

长度不一样,比如原文中的"investigation"错误的译成了"investigatin m"。

3. 由于 ASCII 码在计算机中占 7 个二进制位, 所以我们可以用编码后的二进制码长度和序列长度与 7 的乘积来计算编码效率。

#### 运行结果如下:

## 五 心得与体会
